

Exhibit 4

- Viasat makes WiFi systems including routers.

Mar 25 2018 | Jane Reuter

ViaSat-2 service comes with a powerful wireless router

Advancements in technology enable the Viasat WiFi Gateway to accommodate the higher speeds and faster data flow generated by our ViaSat-2 satellite.

The WiFi Gateway included with our new ViaSat-2 service has a lot in common with its predecessor, but its thoughtful design gives it the power to keep pace with our latest satellite.

Similar to our WiFi Modem, it combines a modem and wireless router that powers your home Wi-Fi network, and is designed to support our VoIP phone service. With advancements in technology made since we designed the WiFi Modem, the Gateway can accommodate the higher speeds and faster data flow generated by our ViaSat-2 satellite.

- The Viasat Wifi Gateway provides WiFi access simultaneously to multiple end units that are located throughout rooms in a building

Inside the WiFi Gateway

As unique as its appearance is, the technology inside the WiFi Gateway is what really sets it apart.

It operates on the latest 802.11 Wi-Fi protocols, standards that ensure networking equipment works with devices created by different vendors. The WiFi Gateway's 802.11ac protocol and antenna design enables the same fast speeds and broad coverage available in the majority of WiFi routers offered by electronics retailers.

The Gateway broadcasts on both 2.4 and 5 gigahertz (GHz) frequency bands. The ability to use both bands means that devices can connect to the frequency band with the best connection, eliminating the need to compromise.

The 2.4 GHz frequency has an extensive range and can more easily pass through obstacles like walls and floors. However, because almost all devices are compatible with this frequency band, the communication channels are narrow, sometimes busy, often are noisy and, as a result, can be slower and less stable at long range. Although it's maximum range is shorter than 2.4, the 5 GHz band is less commonly used and is not as susceptible to other sources of interference, making it a great second option for compatible devices.

<https://www.viasat.com/about/newsroom/blog/viasat-2-service-comes-with-a-powerful-wireless-router/>

➤ **The Viasat Wifi Gateway has video streaming capabilities**

A new way of managing video

Much of the new & improved software is contained within the aforementioned satellite, SANs, TRIAs, and WiFi Gateway. But we've also introduced a new way of optimizing video that's at the heart of our unlimited plans. The reason for this is related to a change in how people like to get their entertainment. With the shift toward "cord cutting" — where people tired of paying for cable TV choose instead to stream shows over the internet with services like Netflix — we knew we had to offer a service to accommodate all this streaming.

Video streaming uses a lot of bandwidth, and that ever-growing amount of data consumption can challenge any network. Our solution was to give people the option to stream video at different rates while still offering an unlimited experience. If you primarily watch TV and movies on a phone or tablet, you might be fine with lower resolution streaming at 360p. If you need higher resolution for watching on larger screens, we offer those options as well. The ability to manage all this is made possible by a sophisticated platform that optimizes all of those video streams, allowing more of our customers to watch more video.

<https://www.viasat.com/about/newsroom/blog/satellite-innovations/>

➤ **The Viasat Wifi Gateway supports MU-MIMO and beamforming technologies**

Further boosting the WiFi Gateway's performance, it's built with a wireless technology that uses multiple transmitters and receivers to transfer more data at one time. Our device is capable of 3x3 Multi-User, Multiple-Input Multiple-Output (MU-MIMO), which transmits and receives three simultaneous streams on information. That's like using a three-lane highway instead of a one-lane road; with a 3x3 MU-MIMO, your data can get around back-ups and other interference and to its destination more without slowing down.

Customer-premises equipment

From Wikipedia, the free encyclopedia

In [telecommunications](#), a **customer-premises equipment** or **customer-provided equipment (CPE)** is any [terminal](#) and associated equipment located at a [subscriber's premises](#) and connected with a [carrier's telecommunication circuit](#) at the [demarcation point](#) ("demarc"). The demarc is a point established in a building or complex to separate customer equipment from the equipment located in either the distribution infrastructure or [central office](#) of the [communications service provider](#).

[CPE](#) generally refers to devices such as [telephones](#), [routers](#), [network switches](#), [residential gateways \(RG\)](#), [set-top boxes](#), [fixed mobile convergence](#) products, [home networking](#) adapters and Internet access [gateways](#) that enable consumers to access providers' communication services and distribute them in a residence or enterprise with a [local area network \(LAN\)](#).

https://en.wikipedia.org/wiki/Customer-premises_equipment

For example, a system is an organized collection of subsystems that are highly integrated to accomplish an overall goal.

People also ask

What is a system simple definition?

Simply put, a **system** is an organized collection of parts (or subsystems) that are highly integrated to accomplish an overall goal. The **system** has various inputs, which go through certain processes to produce certain outputs, which together, accomplish the overall desired goal for the **system**.

<https://managementhelp.org> › defn-system 

Definition of a System

<https://managementhelp.org/systems/defn-system.pdf>

For example, a wireless router is an integrated collection of components (input ports, output ports, switching fabric and a routing processor), which makes it a system. It is used in a home to provide Wi-Fi access. Therefore, a wireless router is a Customer Premise System.

People also ask

What are the components of a wireless router? ^

A generic **router** has four **components**: input ports, output ports, a switching fabric, and a routing processor. An input port is the point of attachment for a physical link and is the point of entry for incoming packets. Ports are instantiated on line cards, which typically support 4, 8, or 16 ports.

According to the patent specification, a customer premise system (also referred to as a wireless distribution system in the patent) does not include end points. For example:

BRIEF SUMMARY OF THE INVENTION

This invention relates to a wireless distribution system for home or business comprising a unitary distribution box, called a wireless multimedia center (WMC), which has inputs for receiving signals from one or more of: a satellite dish; a terrestrial antenna such as a VHF/UHF; a cable line; a telephone or data line such as ISDN, DSL, etc.; and/or fiber optic line, and any other future data or program sources can also be transparently input to the WMC with appropriate modifications or modular plug-ins.

BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWING

FIG. 1 is a block diagram of a unified multimedia distribution system of the present invention

DETAILED DESCRIPTION OF THE INVENTION

As in FIG. 1, this invention relates to a wireless distribution system for home or business, comprising a unitary distribution box 2, called a wireless multimedia center (WMC), which has inputs for receiving signals 11-14 from one or more of:

- a satellite dish 21;
- a terrestrial antenna 22;
- a cable input/output line 23; and/or
- a telephone or data line 24 [ISDN, DSL, etc].

US9344183 vs. 802.11n/ac (Wi-Fi) Wireless Routers and Access Points

Summary:

This chart compares claims 1 of US9344183 to 802.11n/ac compliant wireless routers and access points. Claim 1 is directed to a system for distributing orthogonal frequency division multiplexing (OFDM) signals carrying multimedia information throughout a multi-room building to multiple end units. A key aspect of the claim that differentiates it from earlier versions of the 802.11 standard (a/b/g) is it requires transmission in multiple directions to multiple end units. This function is supported by multiple-input multiple-output (MIMO) technology, which was introduced in 2009 by 802.11n and later improved in 2013 by 802.11ac. Future versions of the 802.11 standard will also use MIMO technology.

With a priority date of February 29, 2000, US9344183 predates the 802.11ac standard by 13 years and the 802.11n standard by 9 years. These standards use orthogonal frequency division multiplexing as well as multiple-input multiple-output (MIMO) technology both of which compensate for multi-path transmission effects that occur from radio frequency (RF) line of sight (LOS) and RF non-LOS transmission paths, such as occur in multi-room buildings. OFDM technology provides adequate symbol width and guard intervals so as to alleviate inter symbol interference (ISI) effects such as can occur due to multi-path, reflection and absorption phase induced losses. When using broadcast/multicast transmission, 802.11n/ac routers and access points do not expect acknowledgement (ACK) messages from the end-users devices upon the successful reception of packets. In 2009, IEEE 802.11n introduced MIMO directed beamforming techniques, which supported maximum of four space-time streams per transmission. This feature provided the capability to direct transmissions to one or more diversely located end units. IEEE 802.11ac increases the maximum number of space-time streams to eight.

a distribution box located in one of the rooms of the indoor, multi-room, building environment and having at least one input for receiving a signal from at least one of a wireless source and a wired source,	The multimedia device (wireless distribution system) comprises a unitary distribution box, called a wireless multimedia center. [1:29-32] The wireless multimedia center receives signals from various sources such as: a satellite dish, a terrestrial antenna, a DSL or fiber optic line [1:33-34], and transmits segments of the signals to individual transceivers, called end units (EU), located throughout the premises. [1:40-43] The signals are from data	<p><u>Commentary:</u></p> <p>An IEEE 802.11n/ac compliant wireless router has a Wide Area Network (WAN) port for connecting to a broadband modem. The broadband modem connects to an Internet service provider via a Cable, DSL, fiber optic line, or terrestrial antenna to receive signals carrying data that provides the Internet service. The Internet service provides many different data and program sources from servers connected to the Internet. The wireless router uses 802.11n/ac (Wi-Fi) to communicate wirelessly to multiple Wi-Fi clients simultaneously. The coverage area of a Wi-Fi network can be extended by connected to the wireless router to multiple Access Points (AP) is physically diverse locations.</p> <p><u>Evidence:</u></p> <p>“Router: This is the central device of a home network into which you can plug one end of a</p>

<i>US9344183 – CLAIM 1</i>	<i>Claim Element Interpretation & Support [patent column: lines]</i>	<i>Commentary & Evidence</i> {References at end}
	<p>or program sources. [1:32-35] Each end unit communicates with the WMC to control which segments the WMC distributes to the end unit. [Abstract]</p>	<p>network cable. The other end of the cable goes into a networking device that has a network port. If you want to add more network devices to a router, you'll need more cables and more ports on the router. These ports, both on the router and on the end devices, are called Local Area Network (LAN) ports.” {3}</p> <p>“Wide-area network (WAN) port: Also known as the internet port. Generally, a router has just one WAN port. (Some business routers come with dual WAN ports, so one can use two separate internet services at a time.) On any router, the WAN port will be separated from the LAN ports, and is often distinguished by being a different color. A WAN port is used to connect to an internet source, such as a broadband modem.” {3}</p> <p>“Broadband modem: Often called a DSL modem or cable modem, a broadband modem is a device that bridges the internet connection from a service provider to a computer or to a router, making the internet available to consumers.” {3}</p> <p>“A wireless network is very similar to a wired network with one big difference: devices don't use cables to connect to the router and one another. Instead, they use radio wireless connections called Wi-Fi (Wireless Fidelity), which is a friendly name for the 802.11 networking standards supported by the Institute of Electrical and Electronics Engineers (IEEE). Wireless networking devices don't need to have ports, just antennas, which sometimes are hidden inside the device itself. In a typical home network, there are generally both wired and wireless devices, and they can all talk to one another. In order to have a Wi-Fi connection, there needs to be an access point and a Wi-Fi client.” {3}</p> <p>“Access point: An access point (AP) is a central device that broadcasts a Wi-Fi signal for Wi-Fi clients to connect to. Generally, each wireless network, like those you see popping up on your phone's screen as you walk around a big city, belongs to one access point. You can buy an AP separately and connect it to a router or a switch to add Wi-Fi support to a wired network, but generally, you want to buy a wireless router, which is a regular router (one WAN port, multiple LAN ports and so on) with a built-in access point. Some routers even come with more than one access point (see discussion of dual-band and tri-band</p>

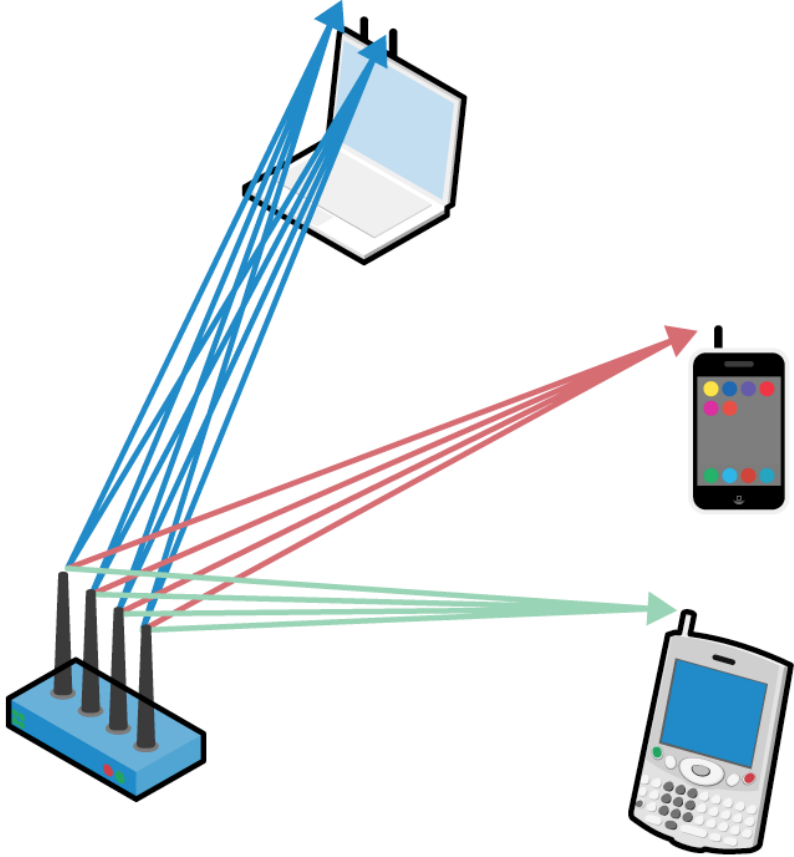

<i>US9344183 – CLAIM 1</i>	<i>Claim Element Interpretation & Support [patent column: lines]</i>	<i>Commentary & Evidence</i> {References at end}
		<p>routers below).” {3}</p> <p>“Wi-Fi client: A Wi-Fi client or WLAN client is a device that can detect the signal broadcast by an access point, connect to it and maintain the connection. All recent laptops, phones and tablets on the market come with built-in Wi-Fi capability.” {3}</p>
the signal having at least one of an audio component and a video component; and	The signals include video or audio signals and broadband data. [5: 36-37] The signals provide distribution of multiple services such as telephone, radio, television, digital data, and Internet throughout the location by wireless digital transmission to end units. [4:64-5:2]	<p>Commentary:</p> <p>The wireless signals transmitted by an 802.11n/ac compliant wireless router or access point include signals for video streaming and broadband data communications.</p> <p><u>Evidence:</u></p> <p>“802.11ac is the latest evolution of Wi-Fi, and it should be particularly good for gaming and HD video streaming.” {4}</p> <p>“The single-link and multi-station enhancements supported by 802.11ac enable several new WLAN usage scenarios, such as simultaneous streaming of HD video to multiple clients throughout the home, rapid synchronization and backup of large data files, wireless display, large campus/auditorium deployments, and manufacturing floor automation.” {1}</p> <p>“The last major revision to the main WiFi standard was 802.11ac, which was designed to dramatically increase the speed of data transfers. This is the first standard on the way to “Gigabit WiFi” where speeds can reach 1 Gbit/s, by far the fastest WiFi version to date. 802.11ac also runs solely on the less cluttered 5 GHz band and this higher frequency and modulation rate allows for a higher speed, at the expense of range compared with 2.4 GHz 802.11n or g.” {5}</p>
an orthogonal frequency division multiplexing (OFDM) transceiver operatively connected to the at least one input of the distribution	Signals input to the multimedia device (wireless multimedia center) are then re-broadcast using OFDM technology throughout the premises. These signals are	<p><u>Commentary:</u></p> <p>IEEE 802.11 n/ac routers and access points use OFDM transmission techniques. They also supports MIMO transmission, which uses multiple input and multiple output antennas to improve signal transmission in indoor environments. MIMO also provides beamforming</p>

<i>US9344183 – CLAIM 1</i>	<i>Claim Element Interpretation & Support [patent column: lines]</i>	<i>Commentary & Evidence</i> {References at end}
box,	transmitted to and received by individual transceivers, called end units (EU), located throughout the premises. [1:38-43] The video signals are broadcast to one or more end units. [5:48] The OFDM that carries the video signals may be coded orthogonal frequency division multiple access (COFDMA). [6:22-23]	<p>capabilities.</p> <p><u>Evidence:</u></p> <p>“Traditionally, radio engineers treated natural multipath propagation as an impairment to be mitigated. MIMO is the first radio technology that treats multipath propagation as a phenomenon to be exploited. MIMO multiplies the capacity of a radio link by transmitting multiple signals over multiple, co-located antennas. This is accomplished without the need for additional power or bandwidth. Space-time codes are employed to ensure that the signals transmitted over the different antennas are orthogonal to each other, making it easier for the receiver to distinguish one from another. Even when there is line of sight access between two stations, dual antenna polarization may be used to ensure that there is more than one robust path.</p> <p>OFDM enables reliable broadband communications by distributing user data across a number of closely spaced, narrowband subchannels.^[1] This arrangement makes it possible to eliminate the biggest obstacle to reliable broadband communications, intersymbol interference (ISI). ISI occurs when the overlap between consecutive symbols is large compared to the symbols’ duration. Normally, high data rates require shorter duration symbols, increasing the risk of ISI. By dividing a high-rate data stream into numerous low-rate data streams, OFDM enables longer duration symbols. A cyclic prefix (CP) may be inserted to create a (time) guard interval that prevents ISI entirely. If the guard interval is longer than the delay spread—the difference in delays experienced by symbols transmitted over the channel—then there will be no overlap between adjacent symbols and consequently no intersymbol interference. Though the CP slightly reduces spectral capacity by consuming a small percentage of the available bandwidth, the elimination of ISI makes it an exceedingly worthwhile tradeoff. “{6}</p>
and operative for wirelessly and unidirectionally broadcasting the signal using OFDM modulation inside the indoor, multi-room, building environment	The definition of broadcasting data packets is well known to those skilled in the art of data communications.	<p><u>Commentary regarding broadcasting:</u></p> <p>IEEE 802.11n/ac supports broadcast transmission of data frames, in which case there the receiving end unit does not send an acknowledgement when it receives a data frame. In IEEE 802.11n (2009) the nomenclature for broadcast and multicast frames changed to</p>

<i>US9344183 – CLAIM 1</i>	<i>Claim Element Interpretation & Support [patent column: lines]</i>	<i>Commentary & Evidence</i> {References at end}
	<p>This patent claims priority from counterpart patent US7827581, which incorporated into this patent (US9344183) by reference. US7827581 includes a definition of broadcasting data packets. This explicit definition is consistent with the accepted meaning of the term. According to this definition, broadcasting digital data packets to transmit digital data packets in one direction (unidirectionally), with no hand-shaking mechanism for each digital data packet.</p> <p>In the example of a residential property, the services are distributed throughout a house. A single multimedia device (wireless multimedia center) distributes the services shown in Fig. 5 to end units located in the various rooms of the home. [3:36-40]</p>	<p>“group addressed” frames. Generally, group addressed frames are frames that are addressed to more than one destination. The Quality of Service (QoS) control field of a data frame is a 16-bit field that identifies the traffic category or traffic stream to which the frame belongs and other QoS-related information about the frame. The Ack Policy subfield (bits 5 and 6) of the QoS control field is used to specify whether or not the data frame requires an acknowledgement. The combination of bit 5 = 1 and bit 6 = 0 is used for group addressed data frames to indicate that an acknowledgement is not required for the data frame.</p> <p>Live streaming, such as sport events etc., frequently use Real Time Streaming Protocol (which runs over Real-time Transport Protocol, which in turn runs over UDP – User Datagram Protocol) because time delays can not be tolerated. Hence UDP is used because it does not perform retransmissions to correct data transmission errors nor does it perform handshaking between the transmitting station and receiving station. {12} {13} {14} Therefore, such transmission are broadcast transmissions as defined by the patent specification (note that US7827581, which specifically defines broadcasting as transmissions that do not perform handshaking is incorporated by reference into US9344183) and are spatially unidirectional by virtue of beamforming as described in the next section of this chart.</p> <p><u>Evidence regarding broadcasting:</u></p> <p>“Frames transmitted to a broadcast or multicast destination (Address 1 has the group bit set) have a duration of 0. Such frames are not part of an atomic exchange and are not acknowledged by receivers, so contention-based access to the medium can begin after the conclusion of a broadcast or multicast data frame.” {2}</p>

<i>US9344183 – CLAIM 1</i>	<i>Claim Element Interpretation & Support [patent column: lines]</i>	<i>Commentary & Evidence</i> {References at end}
from the distribution box in the room in multiple directions	The limitation regarding “in multiple directions to a plurality of end units”, is taken to mean that the broadcast transmission is directionally specific as opposed to being omnidirectional. The transmission is made in the direction of the end units. Furthermore, the wireless multimedia center is capable of directing a transmission to a specific end unit. An end unit informs the WMC of the signal segment that the end unit is to receive. The WMC then directs a transmission of that signal segment, which is receivable by the end unit, to that end unit. [2:65-3:2]. One of the dimensions of the transmission is direction. [6:50]	<u>Commentary</u> In 2009, IEEE 802.11n introduced MIMO transmission capability, which supports directed beamforming. Beamforming enables transmissions to be spatially directed to a one or more diversely located receivers. In 2013, IEEE 802.11ac extended the maximum number of space-time streams supported from four streams in 802.11n to eight in 802.11ac. The Very High Throughput (VHT) physical specification (PHY) of 802.11ac applies to individually addressed and group addressed transmission (see the earlier discussion regarding broadcast/multicast transmissions now referred to as group addressed transmissions). The VHT PHY also provides support for downlink multi-user (MU) transmissions. A downlink MU transmission supports up to four users with up to four space-time streams per user with the total number of space-time streams not exceeding eight. The following figure depicts directed space-time streams being transmitted to end units. Note that either the transmission depicted by the blue arrows (i.e. eight streams) or the transmission depicted by the green arrows and the red arrows (i.e. total of eight streams) would occur simultaneously, so as not to exceed the maximum of eight streams. <u>Evidence:</u> “22. Very High Throughput (VHT) PHY specification 22.1 Introduction 22.1.1 Introduction to the VHT PHY Clause 22 specifies the PHY entity for a very high throughput (VHT) orthogonal frequency division multiplexing (OFDM) system. In addition to the requirements in Clause 22, a VHT STA shall be capable of transmitting and receiving PPDUs that are compliant with the mandatory PHY specifications defined in Clause 20. The VHT PHY is based on the HT PHY defined in Clause 20, which in turn is based on the OFDM PHY defined in Clause 18. The VHT PHY extends the maximum number of space-time streams supported to eight and provides support for downlink multi-user (MU) transmissions. A downlink MU transmission supports up to four users with up to four space-time streams per user with the total number of space-time streams not exceeding

<i>US9344183 - CLAIM 1</i>	<i>Claim Element Interpretation & Support [patent column: lines]</i>	<i>Commentary & Evidence</i> {References at end}
at least one of the end units being located in another room separated by a wall from the one room of the indoor, multi-room, building environment,	In the example of a residential property, the services are distributed throughout a house. A single multimedia device (wireless multimedia center) distributes the services shown in Fig. 5 to end units located in the various rooms of the home. [3:36-40]	<p><u>Commentary:</u></p> <p>Transmissions from IEEE 802.11n/ac compliant routers and access points are capable of passes through walls of an indoor, multi-room building. The excerpt from the referenced research paper describes an office scenario in which an 802.11ac access point was tested. The access point is depicted as a blue square in the figure. Wireless devices at locations E, G, and H receive non-line of sight transmissions through at least one interior wall. IEEE 802.11n routers and access points are thought to have better wall penetration capability than similar 802.11ac systems because they transmit at 2.4 GHz, as compared to 802.11ac systems, which transmit at 5 GHz. Although some 802.11ac routers and access point support dual frequencies - 2.4Ghz and 5 GHz.</p> <p><u>Evidence:</u></p> <p>“3. 802.11AC THROUGHPUT & JITTER PERFORMANCE CHARACTERIZATION</p> <p>3.1 Office scenario</p> <p>We deploy an indoor 802.11ac WLAN testbed in our offices, covering an area of 40×15m2. The office testbed is depicted in Fig. 1 with the blue square indicating the AP and the red circles the clients. The average RSSI and other characteristics of each client evaluated in the office testbed are described in Table 1. “{10}</p>

		other solid objects. 5Ghz by contrast, is what we’ll call the “indoor” band. It’s ideal for connections inside the house due to the lack of congestion, higher data transmission rates, and smaller effective range. It’s also the only band available if you want to take advantage of the newer, super-fast wireless AC standard. {11}
the at least one end unit receiving the unidirectionally broadcast signal through the wall via packets each having a width of sufficient duration to resist multi-path reflection and absorption phase induced losses.	Signals input to the multimedia device (wireless multimedia center) are then re-broadcast using OFDM technology throughout the premises. These signals are transmitted to and received by individual transceivers, called end units (EU), located throughout the premises. [1:38-43] All of the signals are added together and summed as an orthogonal array having dimensions of time, frequency and amplitude, to transmit spread spectrum multiplexed signals, in which each pulse including said signals has sufficiently long individual pulse widths to defeat multi-path, reflection and absorption phase induced losses. [5:42-47]	<p>Commentary:</p> <p>IEEE 802.11n/ac compliant routers and access points use OFDM transmission techniques that enable the transmission to resist multi-path reflection and absorption phase induced losses. The first references compares 802.11ac transmission testing (link quality) results between an office testbed, in which the interior walls were made of concrete and steel, to a home testbed, in which the interior walls were made of wood. In both cases the transmissions penetrated the interior walls, even though the walls made of concrete and steel provided a higher degree of reflections and multi-path effects. The second reference describes how OFDM signals resist these effects. Specifically, by distributing the data across multiple subchannels, the data rate on each subchannel is slow enough that the transmitted data symbols are of long enough duration to resist intersymbol interference, which is caused by the effects of multi-path reflection and absorption phase induced losses. Therefore, the transmitted packets, which comprise these symbols, are of sufficient duration to resist these effects.</p> <p>Evidence:</p> <p>“3.2 Home scenario</p> <p>To validate that the results presented in §3.1 are consistent in more than one testbed, we repeat the same characterization with the same methodology in a home testbed covering an area of 18 × 15m² (mainly built of wood). The links evaluated are described in Table 4. Note that we examined multiple different areas of the home environment but there was</p>

<i>US9344183 – CLAIM 1</i>	<i>Claim Element Interpretation & Support [patent column: lines]</i>	<i>Commentary & Evidence</i> {References at end}
		<p>not high variation in link qualities and therefore we only present four links.</p> <p>We see that the trend of the office regression (Fig. 3) heatmaps is similar is followed also in the case of the home testbed (Fig. 4). However, the trend for each feature in the home testbed is much clearer and more monotonic and consistent across the different link qualities because of the lack of high human interference, as well as the material (wood) the home testbed is made of – compared to the office one (concrete, steel) – minimizing the impact of reflections and multipath. “{10}</p> <p>“OFDM enables reliable broadband communications by distributing user data across a number of closely spaced, narrowband subchannels.^[1] This arrangement makes it possible to eliminate the biggest obstacle to reliable broadband communications, intersymbol interference (ISI). ISI occurs when the overlap between consecutive symbols is large compared to the symbols’ duration. Normally, high data rates require shorter duration symbols, increasing the risk of ISI. By dividing a high-rate data stream into numerous low-rate data streams, OFDM enables longer duration symbols. A cyclic prefix (CP) may be inserted to create a (time) guard interval that prevents ISI entirely. If the guard interval is longer than the delay spread—the difference in delays experienced by symbols transmitted over the channel—then there will be no overlap between adjacent symbols and consequently no intersymbol interference. Though the CP slightly reduces spectral capacity by consuming a small percentage of the available bandwidth, the elimination of ISI makes it an exceedingly worthwhile tradeoff. “{6}</p>
